Executive summary

This report represents the results of the engagement with **Xave Finance** to review **Xave Lending Market**.

The review is part of a broader engagement with Xave Finance that also includes the Xave AMM component.

The full review was conducted over the course of **2 weeks** from **October 18th to October 29th, 2021**. We spent a total of **15 person-days** reviewing the code.

Scope

The initial review focused on the Xave Lending Market repository, identified by the commit hash `01486a398b0aa36b9798ba06fce11b5d3376909d`.

We focused on manually reviewing the codebase, searching for security issues such as, but not limited to, re-entrancy problems, transaction ordering, block timestamp dependency, exception handling, call stack depth limitation, integer overflow/underflow, self-destructible contracts, unsecured balance, use of origin, costly gas patterns, architectural problems, code readability.

Includes:

- code/contracts/buyback/Treasury.sol
- code/contracts/buyback/interfaces/ICurve.sol
- code/contracts/buyback/interfaces/ICurveFactory.sol
- code/contracts/buyback/interfaces/IUniswapV2Router01.sol
- code/contracts/buyback/interfaces/IUniswapV2Router02.sol
- code/contracts/incentives/RnbwDistributionManager.sol
- code/contracts/incentives/RnbwIncentivesController.sol
- code/contracts/incentives/VersionedInitializable.sol

- code/contracts/incentives/interfaces/IAToken.sol
- code/contracts/incentives/interfaces/IERC20.sol
- code/contracts/incentives/interfaces/IERC20Detailed.sol
- code/contracts/incentives/interfaces/IRnbwDistributionManager.sol
- code/contracts/incentives/interfaces/IRnbwIncentivesController.sol
- code/contracts/incentives/interfaces/IStakedAave.sol
- code/contracts/incentives/lib/Context.sol
- code/contracts/incentives/lib/DistributionTypes.sol
- code/contracts/incentives/lib/ERC20.sol
- code/contracts/incentives/lib/SafeMath.sol

Recommendations

We identified a few possible general improvements that are not security issues during the review, which will bring value to the developers and the community reviewing and using the product.

Increase the number of tests

A good rule of thumb is to have 100% test coverage. This does not guarantee the lack of security problems, but it means that the desired functionality behaves as intended. The negative tests also bring a lot of value because not allowing some actions to happen is also part of the desired behavior.

Issues

`Treasury.buybackRnbw()` is vulnerable to price manipulation attacks

Status Open Severity Medium

Description

The owner of the `Treasury` can call the `buybackRnbw` function to convert one or more of the underlying tokens within a lending pool to `rnbw` tokens:

code/contracts/buyback/Treasury.sol#L44

```
function buybackRnbw(address[] calldata _underlyings) external onlyOwner returns (uint256) {
```

The function first uses the cloned DFX protocol to convert the token into USDC:

code/contracts/buyback/Treasury.sol#L81-L88

```
uint256 targetAmount =
  ICurve(curveAddress).originSwap(
    _underlying,
    USDC,
    _underlyingAmount,
    0,
    block.timestamp + 60
  );
```

After that the Uniswap V2 protocol is used to convert from USDC to RNBW tokens:

code/contracts/buyback/Treasury.sol#L59-L69

```
address[] memory path = new address[](3);
path[0] = USDC;
path[1] = WETH9;
path[2] = rnbw;
rnbwBought = IUniswapV2Router02(router).swapExactTokensForTokens(
  usdcBalance,
  0,
  path,
  address(this),
  block.timestamp + 60
)[0];
```

The issue is that in both token swap cases above, the arguments `amountOutMin` (for Uniswap) and `_minTargetAmount` (for DFX Curve contract) are passed as `0` values. This means that the `Treasury` contract does not enforce any minimum amount expected for the output of RNBW tokens swapped.

The reason why the above two implementations are vulnerable to price manipulation is explained in the Uniswap V2 **Safety Considerations** section:

> Because Ethereum transactions occur in an adversarial environment, smart contracts that do not perform safety checks can be exploited for profit. If a smart contract assumes that the current price on Uniswap is a "fair" price without performing safety checks, it is vulnerable to manipulation. A bad actor could e.g. easily insert transactions before and after the swap (a "sandwich" attack) causing the smart contract to trade at a much worse price, profit from this at the trader's expense, and then return the contracts to their original state. (One important caveat is that these types of attacks are mitigated by trading in extremely liquid pools, and/or at low values.)

Recommendation

The best way to protect against these attacks is to use an external price feed or "price oracle". The best "oracle" is simply traders' off-chain observation of the current price, which can be passed into the trade as a safety check.

The `buybackRnbw` function can accept an additional parameter `minRNBWAmount` that can be checked after the two above steps are performed, or passed to the `swapExactTokensForTokens` Uniswap function, to ensure that an expected minimum amount of RNBW tokens were received by the `Treasury` contract.

For example, Uniswap V2 getAmountsOut can be used by a frontend to calculate a fair value for USDC / RNBW:

> Given an input asset amount and an array of token addresses calculates all subsequent maximum output token amounts by calling getReserves for each pair of token addresses in the path in turn, and using these to call getAmountOut.
>
> Useful for calculating optimal token amounts before calling swap.

Rapid Rise of MEV in Ethereum

WETH9 state variable can be made constant to save gas costs

Description

`WETH9` state variable never changes therefore it can be defined as a constant to save gas costs:

code/contracts/buyback/Treasury.sol#L26

```
address public WETH9 = 0xC02aaA39b223FE8D0A0e5C4F27eAD9083C756Cc2;
```

Reuse openzeppelin libraries

Description

In most cases the code makes use of the OpenZeppelin's standard libraries:

code/contracts/buyback/Treasury.sol#L7-L9

```
import {SafeMath} from '@openzeppelin/contracts/math/SafeMath.sol';
import {Ownable} from '@openzeppelin/contracts/access/Ownable.sol';
import {IERC20} from '@openzeppelin/contracts/token/ERC20/IERC20.sol';
```

In other cases, however, the code uses copy-pasted versions of the same libraries:

code/contracts/incentives/RnbwIncentivesController.sol#L6-L8

```
import {SafeMath} from './lib/SafeMath.sol';

import {IERC20} from './interfaces/IERC20.sol';
```

Below we show that there are not functional differences between the `./incentives/lib/Context.sol` file and the one that comes with OpenZeppelin:

```
$ diff -uN --ignore-all-space ./incentives/lib/Context.sol ../node_modules/@openzeppelin/contracts/GSN/Con
--- ./incentives/lib/Context.sol        2021-10-22 08:00:48.000000000 +0700

Recommendation

Remove the following contracts from `./code/contracts/incentives/lib/` folder and make use of the version provided with OpenZeppelin: `Context`, `ERC20`, `MintableErc20`, `SafeMath`.

Unnecessary future `deadline` value passed to swap functions

Status Open Severity Minor

Description

`Treasury.buybackRnbw()` uses Uniswap V2 to convert underlying tokens into USDC:

code/contracts/buyback/Treasury.sol#L63-L69

```
    rnbwBought = IUniswapV2Router02(router).swapExactTokensForTokens(
      usdcBalance,
      0,
      path,
      address(this),
      block.timestamp + 60
    )[0];
```

The `deadline` argument passed to `swapExactTokensForTokens` function is 60 blocks into the future. The deadline parameter is useful for frontend and other off-chain software to ensure there's a deadline after which a swap transaction will revert.

In this case, passing just `block.timestamp` is enough to ensure correct behavior:

Uniswap's `swapExactTokensForTokens` definition:

```
    function swapExactTokensForTokens(
        uint amountIn,
        uint amountOutMin,
        address[] calldata path,
        address to,
        uint deadline
    ) external override ensure(deadline) returns (uint[] memory amounts) {
```

Uniswap `ensure` modifier:

```
    modifier ensure(uint deadline) {
        require(deadline >= block.timestamp, 'UniswapV2Router: EXPIRED');
        _;
    }
```

Recommendation

Instead of `block.timestamp + 60` just pass `block.timestamp` as the deadline argument to `swapExactTokensForTokens` call.

Notes

A similar change can be made to the `originSwap` call:

code/contracts/buyback/Treasury.sol#L81-L88

```
    uint256 targetAmount =
      ICurve(curveAddress).originSwap(
        _underlying,
        USDC,
        _underlyingAmount,
        0,
        block.timestamp + 60
      );
```

The issue here though is that you still need to add `+1` to the `block.timestamp` because of the way the `deadline` modifier in `Curve.sol` is defined. Because of this, we leave it to the Xave Finance team the decision change the call to `originSwap` since there are no (gas) benefits, although it might provide more clarity to the reader:

```
    modifier deadline(uint256 _deadline) {
        require(block.timestamp < _deadline, "Curve/tx-deadline-passed");
        _;
    }
```

Remove obsolete modifier in `Treasury` contract

Status Open Severity Informational

Description

The `onlyEOA` modifier is obsolete and can be removed:

code/contracts/buyback/Treasury.sol#L98-L101

```
modifier onlyEOA() {
  require(msg.sender == tx.origin, 'Only EOA allowed');
  _;
}
```

Artifacts

Surya

Sūrya is a utility tool for smart contract systems. It provides a number of visual outputs and information about the structure of smart contracts. It also supports querying the function call graph in multiple ways to aid in the manual inspection and control flow analysis of contracts.
